## 0.1 # WeatherPy

### 0.1.1 Analysis

- As expected, cities in the latitudes of approximately -20 to 20 degrees had the highest max temperatures.
- There were no strong relationships that could be observed between latitude and humidity. (Oddly, when the analysis was run initially, there was one city that had >300% humidity that may have been an error in recording, so added an extra step to remove any observation points that had >100% humidity. When run again, there were no outliers but kept the filtering step in the code.)
- There were no observable relationships between latitude and cloudiness.
- There were no observable relationships between latitude and wind speed. There seems to be more cities that have greater than 5 mph wind speeds in the northern hemisphere, but this is most likely due to the fact that there are more cities in the northern hemisphere, and not an indication of a relationship between latitude and wind speeds.

# Create a set of random lat and lng combinations

lat_lngs = zip(lats, lngs)

# Identify nearest city for each lat, lng combination
for lat_lng in lat_lngs:
    city = citipy.nearest_city(lat_lng[0], lat_lng[1]).city_name

### 0.2.1 Perform API Calls

- Perform a weather check on each city using a series of successive API calls.
- Include a print log of each city as it's being processed (with the city number and city name).

```
In [3]: # Created a function that will pull desired data from the weather API

    response = requests.get(query_url)
    out_json = response.json()

    try:
        print(f"Processing record for {city}.")
        print(query_url)
